Dear Mr. Carlson:

Enclosed please find the *June 2014 Annual Monitoring Report for FGGM-17, Closed Sanitary Landfill, Fort George G. Meade, Maryland* (Report). The Report provides the results of the March 2014 sampling event along with historical data.

Copies of this Report have been furnished to John Burchette (U.S. Environmental Protection Agency), Mick Butler (Fort George G. Meade), Francis Coulters (U.S. Army Environmental Command), Elisabeth Green (Maryland Department of Environment), and the Fort George G. Meade Restoration Advisory Board.

If you have any questions please feel free to contact Denise Tegtmeyer at (301) 677-9559 or me at (301) 677-7999.

Sincerely,

George B. Knight, PG

Executive Summary

This report presents the results of the annual groundwater and surface water monitoring completed at the Closed Sanitary Landfill (CSL) (FGGM-17) at Fort George G. Meade (FGGM) in Anne Arundel County, Maryland in March 2014. The FGGM CSL is located in the southeastern portion of the base, south of U.S. Route 32 and west of the Amtrak railroad right of way. Cell 1 covers approximately 46 acres and Cell 2 covers 24 acres. A third area that lacks topographic expression is referred to informally as Cell 3, but is not a defined disposal area.

ARCADIS U.S., Inc. (ARCADIS) performed all work in accordance with Contract No.W91ZLK-05-D-0015 Task Order 0005 between ARCADIS and the United States Army Environmental Command. Under regulatory guidance including Federal regulations, 40 Code of Federal Regulations Part 258 and state regulations, Code of Maryland Regulation Title 26 Subtitle 04, a detection and assessment monitoring program is required at the CSL. The field effort was conducted between 18 March and 28 March 2014 and included a comprehensive water-level survey and groundwater sampling and analysis for constituents of concern (COCs). A total of 26 monitoring wells were sampled during the annual event.

In samples collected from Upper Patapsco Aquifer (UPA) wells, 23 metals were detected. Four metals (arsenic, cadmium, chromium, and lead) were detected at concentrations exceeding their respective maximum contaminant level (MCL). Twenty-five volatile organic compounds (VOCs) were detected in 12 samples from UPA wells, and 15 of 25 VOCs detected were chlorinated compounds. Benzene was the only VOC detected above its MCL. All other metals and VOCs detected were below MCLs.

In samples from Lower Patapsco Aquifer (LPA) wells, seven VOCs were detected in four samples. Tetrachloroethene and carbon tetrachloride were the only VOC constituents detected above their respective MCL. Beryllium and lead were the only metals detected above their respective MCLs.

Three surface water samples were collected during the March 2014 monitoring event. No metals were detected at concentrations that exceeded State of Maryland Water Quality Criteria. One VOC, acetone, was detected in the sample at SW02 at a concentration below the State of Maryland Water Quality Criteria.

An Addendum to the CSL Monitoring Plan dated 20 June 2012 was prepared in response to comments dated 6 April 2012 from the Maryland Department of the

Environment (MDE) that agreed to the reduction of monitoring frequency of the ten deep LPA wells from semi-annual to annual. Deep LPA groundwater monitoring wells will continue to be monitored on an annual basis moving forward. The correspondence from MDE dated April 6, 2012 also noted that once a corrective action has been approved for Operable Unit 4 / LPA, a request to discontinue monitoring of the deep LPA wells under the CSL Monitoring Program will be re-evaluated. The revised CSL Monitoring Plan reflecting these changes was submitted on 25 February 2013.

1. Introduction

This report presents the results of the annual groundwater and surface water monitoring completed at the Closed Sanitary Landfill (CSL) (FGGM-17) at Fort George G. Meade (FGGM) in Anne Arundel County, Maryland in March 2014. ARCADIS U.S., Inc. (ARCADIS) performed all work in accordance with Contract No.W91ZLK-05-D-0015 Task Order 0005 between ARCADIS and the United States Army Environmental Command. Under regulatory guidance including Federal regulations, 40 Code of Federal Regulations Part 258 and state regulations, Code of Maryland Regulation Title 26 Subtitle 04, a detection and assessment monitoring program is required at the CSL. The field effort was conducted between 18 March and 28 March 2014 and included a comprehensive water-level survey and groundwater sampling and analysis for constituents of concern (COCs). A total of 26 monitoring wells were sampled during the annual event.

2. Environmental Setting

2.1 Background

FGGM is located approximately midway between Washington, D.C. and Baltimore, Maryland in Anne Arundel County, Maryland, as illustrated on the regional map in **Figure 1**. The FGGM CSL is located in the southeastern portion of the base, south of U.S. Route 32 and west of the Amtrak railroad right of way. Cell 1 covers approximately 46 acres and Cell 2 covers 24 acres. A third area that lacks topographic expression is referred to informally as Cell 3, but is not a defined disposal area. Other features in the vicinity of the landfill include surface water retention ponds along a small stream flowing from east to west that bisects the site. A landfill-gas collection and treatment system operates along the eastern edge of the landfill cells to control emissions from the site. Much of the Site, outside of the landfill cells, is wooded and there are several areas identified as wetlands. The Site map for the CSL is provided as **Figure 2**.

2.2 Climate

The climate at FGGM is variable and influenced by the Chesapeake Bay and the Atlantic Ocean to the east and the Appalachian Mountains to the west. The winter weather in the area is influenced primarily by cold, dry, continental-polar winds from the west and northwest, and less frequent maritime-tropical winds from the south and southwest that bring warm, often humid, air to the region. During the summer, the dominance of these two air masses is reversed, and warm, humid weather dominates.

Local weather data are compiled by the National Oceanic and Atmospheric Administration's Climatic Data center for the Baltimore-Washington Thurgood Marshall International Airport weather station. Annual precipitation averages about 40 inches per year. The distribution of precipitation is essentially even throughout the year, although slightly lower averages are posted for the summer months. Historical average monthly precipitation ranges between 2.8 and 3.5 inches for all months. The annual mean daily temperature for the FGGM area is 61 degrees Fahrenheit (°F), with a daily annual maximum of 72°F and minimum of 45°F. Annual temperature extremes vary from -6 to 101°F.

2.3 Topography

FGGM is located in the Coastal Plain physiographic province (Coastal Plain), which is characterized by low-rolling uplands and low-gradient streams. The ground elevation at FGGM generally ranges between 150 and 250 feet (ft) above mean sea level (msl). Ground elevation surveyed at monitoring well locations ranges from 135 to 177 ft above msl.

2.4 Surface Water

FGGM is almost entirely located within the Patuxent River watershed, which is one of the primary drainage systems in Anne Arundel County. The extreme northeastern portion of FGGM is within the Severn River drainage basin. The Patuxent River watershed encompasses approximately 932 square miles and comprises eight sub-basins from north to south:

- Brighton Dam
- Middle Patuxent River
- Little Patuxent River
- Rocky Gorge Dam
- Patuxent River Upper
- Western Branch
- Patuxent River Middle
- Patuxent River Lower

FGGM is predominantly located within the Little Patuxent River sub-basin. Several streams drain FGGM within the Little Patuxent River sub-basin. The streams are, from west to east:

- Little Patuxent River
- Midway Branch
- Franklin Branch

The only significant lake/reservoir present on FGGM is Burba Lake (formerly called Kelly Pool).

At the CSL, there are surface water retention ponds. There is also a small stream flowing from east to west that bisects the Site displayed on **Figure 2**. The unnamed stream enters the east side of the CSL from a culvert under the Amtrak right of way and flows westward through a retention pond between landfill Cells 1 and 2, through wooded wetlands and a retention pond, and exits the Site flowing westward into ponds adjacent to Range Road.

2.5 Geology

FGGM is located just within the western boundary of the Coastal Plain. The Coastal Plain geology is characterized by a wedge of unconsolidated Cretaceous and Quaternary alluvial sediments (unconsolidated sands, silts and clays) that dip and thicken toward the Atlantic Ocean.

West of the Coast Plain is the Piedmont physiographic province (Piedmont), comprising igneous and metamorphic rocks. The boundary between the Piedmont and Coastal Plain is termed the “Fall Line,” after falls and rapids were found where streams cross this boundary. The Fall Line is located near the western Anne Arundel County line, immediately west of FGGM.

Quaternary- and Cretaceous-aged unconsolidated deposits are exposed at the surface at FGGM. These deposits have a total thickness of about 700 ft at FGGM (URS Group Inc. [URS], 2003) and are underlain by bedrock consisting of Precambrian crystalline rock composed predominately of gabbro, gneiss and schist. The unconsolidated deposits from youngest to oldest consist of:

- Quaternary alluvium and Patuxent River terraces
- Patapsco Formation
- Arundel Clay
- Patuxent Formation

The Patuxent Formation is exposed at the surface west of FGGM, the Arundel Clay crops out over the western portion of FGGM, and the Patapsco Formation crops out over the central and eastern portions of FGGM. Quaternary alluvium and river terrace deposits locally overlay the Potomac Group near the Patuxent and Little Patuxent Rivers.

Coastal Plain groundwater predominantly occurs within the following three major Potomac Group aquifers which underlie FGGM:

- Upper Patapsco
- Lower Patapsco
- Patuxent

The upper and lower portions of the Patapsco Formation are locally separated by the Middle Patapsco. Similarly, the Arundel Formation acts as a confining layer that separates the Patuxent Formation from the Lower Patapsco Formation. Extensive and on-going hydrogeological investigations in the southeast corner of FGGM have documented the Middle Patapsco clay as thick and continuous beneath the CSL occurring at depths between approximately 40 to 50 ft below ground surface. The Middle Patapsco clay is approximately 60 to 80 ft in thickness with the Lower Patapsco aquifer occurring beneath it.

3. Monitoring Program

The CSL monitoring program includes 26 monitoring wells. In accordance with the CSL Monitoring Plan dated 25 February 2013, 16 monitoring wells screened in the Upper Patapsco Aquifer (UPA) are sampled semi-annually and ten monitoring wells screened in the Lower Patapsco Aquifer (LPA) are sampled annually. During the March 2014 monitoring event, groundwater samples were collected between 18 March and 28 March 2014. Groundwater parameters monitored under Detection Monitoring and Assessment Monitoring are provided in **Tables 1** and **2**, respectively. **Table 3** presents a summary of analytical methods used during the semi-annual sampling at CSL.

All purging and sampling activities were completed in accordance with procedures outlined in Standard Operating Procedure E.7 – Low-flow Groundwater Purging and Sampling Procedures for Monitoring Wells provided in Appendix A of the FGGM Sampling and Analysis Plan (SAP) (ARCADIS, 2010a). Field parameter measurements, purging observations, sampling methods and materials, sampling personnel, and bottle requirements were recorded on Groundwater Sampling Forms, which are presented in **Appendix A**.

3.1 Well Gauging

The 26 monitoring wells included in the CSL sampling program were gauged for groundwater elevations prior to sampling activities commencing. Water-level measurements were collected using an electronic water level indicator and measurements were recorded on a Water-Level Measurement Form. Water-level measurements were referenced to a surveyed elevation point located on the top of the well casing. Water levels were measured at least two times to check the reproducibility of the measurement data and ensure accuracy before the measurements were recorded. Monitoring well locations, top of well casing elevations, depth to water readings, and groundwater elevations are presented in **Table 4**. Groundwater elevation contour maps for the UPA and LPA are presented as **Figures 3 and 4**, respectively.

Table B-1 in **Appendix B** provides a comparison of the groundwater elevations in March 2014 to the elevations measured in September 2013. Water levels in all UPA wells increased, ranging between 0.05 ft (MW7S) and 2.16 ft (MW20), except in MW105 where the water level decreased by 0.14 ft. Water levels in all the LPA wells decreased, ranging between 0.28 ft (MW13D) and 0.77 ft (MW109D).

3.2 Groundwater Sampling

3.2.1 Purge Methodology

Groundwater samples were collected in accordance with United States Environmental Protection Agency (USEPA) Region III low-flow groundwater purging methodology (USEPA, 1997). To ensure that representative formation water was being sampled, monitoring wells were purged and sampled using a submersible pump and polyethylene tubing. The submersible pump intake was placed mid-screen. In addition, all non-dedicated equipment and materials were decontaminated prior to and after introduction into each of the monitoring wells.

During well purging, field parameters were monitored using a water quality meter with a flow-through cell. These field parameters included pH, specific conductance, turbidity, dissolved oxygen, temperature, and oxidation-reduction potential. Upon stabilization, groundwater samples were collected through the sample tubing.

3.2.2 Sampling Methodology

All groundwater samples were collected directly from the discharge point of the sample tubing connected to the submersible pump. Groundwater samples were preserved, labeled, recorded on a Chain of Custody, and packed on ice for shipment to Shealy Laboratories in West Columbia, South Carolina, for analytical methods identified in **Table 3**. For quality assurance/quality control (QA/QC) purposes, two duplicate samples were collected, and one trip blank was included in each cooler shipped for volatile organic compound (VOC) analysis. One matrix spike and matrix spike duplicate were also collected.

3.3 Surface Water Sampling

Three surface water samples were collected during the March 2014 monitoring event from the sampling stations (SW01, SW02 and SW03) along the stream that crosses the Site. The unnamed stream enters the east side of the CSL from a culvert under the Amtrak right of way and flows westward through a retention pond between landfill Cells 1 and 2, through wooded wetlands and a retention, and exits the Site flowing westward into ponds adjacent to Range Road. The upstream monitoring point SW01 is in the ditch below the railroad embankment along the eastern boundary of the landfill. Surface water sampling location SW02 is the outfall from the retention pond between landfill Cells 1 and 2. Surface water sampling location SW03 is located at the culvert beneath Magazine Road where the stream crosses the western boundary of the Site.

Surface water samples were collected by submerging an unpreserved bottle and pouring that water into the respective pre-preserved bottles. At location SW-1, a thin ice layer was noted during sample collection. In order to collect the surface water sample, the ice was broken and the sample was collected according to normal procedures. When water flow is sufficient at SW02 and SW03 each bottle is filled directly from the outfall. Similar to groundwater sample collection, the surface water VOC sample is collected first, followed by the other parameters in the order of decreasing volatility.

3.4 Quality Assurance/Quality Control and Sample Identification

In accordance with the FGGM Quality Assurance Project Plan (ARCADIS, 2010b), additional samples were collected for QC analysis at the rate of 1 per 20 field samples. Duplicate samples were collected at MW17 and MW110D. One matrix spike and matrix spike duplicate was also collected at MW108D. Daily equipment rinse blanks were also submitted with the groundwater samples each day that non-dedicated sampling equipment was used. Trip blanks were included with any sample cooler containing VOC samples.

Field sample nomenclature was conducted in accordance with the FGGM SAP (ARCADIS, 2010a). Specifically, sample identifications (IDs) were modified to include FM17, an abbreviation for the CSL Site. In addition to the site abbreviation and monitoring well ID, the date the sample was collected is also included in the sample ID in parenthesis. For example, FM17MW4S(032014) would be the ID for the sample collected at well MW4S if it was sampled on 20 March 2014.

The analytical results for all QA/QC samples (i.e., trip blanks and equipment blanks) collected are provided in **Appendix C**. Table C-1 presents a summary of abbreviations, laboratory flags, data validation flags, and data validation reason codes that provide additional information on the data qualifiers. Table C-2 is a summary of the QA/QC detections (the detections-only table) and Table C-3 is the comprehensive listing of all analytes for the QA/QC samples. Table C-4 presents detections above the reliable detection limits and method detection limits (MDLs) from samples collected from both aquifers.

3.4.1 Data Validation

All groundwater data collected during the March 2014 sampling event received level II data validation performed under USEPA guidelines by Laboratory Data Consultants, Inc. located in Carlsbad, California. The validation process establishes whether the data are usable for the intended purpose of evaluating conditions at the site.

The data validation process includes a review of QC data generated in both the field and the laboratory. Trip and equipment blanks provide information on potential sample contamination introduced in the field and in transit to the laboratory. Method blanks, which are generated in the laboratory, are used to assess such factors as the sensitivity, accuracy, reproducibility, and cleanliness. Validation includes reviewing holding times, daily laboratory calibration curves for the analytical instruments, spike recovery, and confirming laboratory standards are current. The validation concluded that the data are usable, as qualified, for the intended purpose of evaluating the groundwater and surface water at the CSL. The data validation reports for the March 2014 data are presented in **Appendix D**.

3.5 Investigative Derived Waste Management

All investigative derived waste (IDW) generated during the sampling event was managed in accordance with procedures outlined in the FGGM Waste Management Plan (WMP) (ARCADIS, 2010c).

3.5.1 Purge Water

Purge water and decontamination fluids were combined before being containerized. All waste was stored in 55-gallon Department of Transportation approved drums, properly labeled and staged in a secure location at the CSL. At the end of the sampling event, all IDW was relocated to the FGGM designated IDW storage area located at 2250 Rock Avenue pending offsite disposal.

3.5.2 Solid Waste

All personal protective equipment and disposable sampling equipment were collected in plastic trash bags and disposed of in accordance with the FGGM WMP (ARCADIS, 2010c).

4. Chemical Results - Groundwater

This section of the report presents analytical results for the March 2014 monitoring program and discusses the distribution of COCs in the UPA and LPA. To assess Site conditions, groundwater results were screened using USEPA Maximum Contaminant Levels (MCLs) and Secondary Maximum Contaminant Levels (SMCLs) for drinking water.

Laboratory analytical results are presented in three tables. UPA positive detections, detections above MCLs, and detections above SMCLs are presented in **Tables 5, 6, and 7**, respectively. LPA positive detections, detections above MCLs, and detections above SMCLs are presented in **Tables 8, 9, and 10**, respectively. Data qualifiers and laboratory abbreviations are provided in **Appendix C**. Full listings of the laboratory results for both aquifers are presented in **Appendix E**. Benzene and arsenic plume contour maps for the UPA are presented as **Figures 5 and 6**, respectively. Trend plots for arsenic and benzene in the UPA are presented as **Figures 7 and 8**, respectively. Tetrachloroethene (PCE) trend plots for the LPA are provided as **Figure 9**.

4.1 Upper Patapsco Aquifer

4.1.1 Summary of Detections

Positive detections in the UPA include pesticides, herbicides, metals, semi-volatile organic compounds (SVOCs), VOCs and miscellaneous parameters as shown on **Table 5**. Explosives were sampled at three UPA monitoring wells but all compounds were not detected above laboratory detection limits.

Pesticides and herbicides were detected at concentrations below MCLs in three groundwater samples. Three herbicides 2,4,5-TP, 2,4-D, and dichlorprop were detected in the sample from well MW19. Ten pesticides, 4,4-dichlorodiphenyltrichloroethane, aldrin, alpha-bhc, beta-bhc, delta-bhc, dieldrin, endosulfane II, endrin ketone, gamma-bhc, and gamma-chlordane, were detected at concentrations below their respective MCLs from the three monitoring wells (MW7S, MW12S, and MW19).

Twenty-three metals were detected in samples from the UPA wells. Four metals (arsenic, cadmium, chromium, and lead) were detected at concentrations exceeding their respective MCL as described in Section 4.1.2. Nine of these (barium, calcium, cobalt, iron, manganese, nickel, potassium, sodium, and zinc) are widespread and appear to be naturally occurring in the UPA. Ten metals (aluminum, antimony, beryllium, copper, magnesium, mercury, selenium, silver, thallium, vanadium) were detected at concentrations below MCLs and were not widespread.

Three SVOCs were detected in one groundwater sample below their respective MCLs. 1,2-dichlorobenzene, 4-Methylphenol, and naphthalene were detected at the sample from MW19.

Twenty-five VOCs were detected in 12 samples from UPA wells, and 15 of 25 VOCs detected were chlorinated compounds. Benzene was the only VOC detected above its MCL as described in Section 4.1.2. All other VOCs detected were below MCLs.

4.1.2 Summary of Exceedances above Maximum Contaminant Levels and Secondary Maximum Contaminant Levels

The UPA analytical results were screened against MCLs and SMCLs, as shown on **Tables 6 and 7**, respectively. Six analytes exceeded their MCLs:

- Arsenic exceeded its MCL of 10 micrograms per liter (µg/L) in five samples at concentrations between 11 µg/L (MW18) and 43 µg/L (MW19).
- Benzene exceeded its MCL of 5 µg/L in the sample from MW19 (11 µg/L).
- Cadmium exceeded its MCL of 5 µg/L in the sample from MW14 (6.6 µg/L).
- Chromium exceeded its MCL of 100 µg/L in the sample from MW14 (3000 µg/L). It should be noted that this chromium detection is a historical maximum. Chromium exceeded its MCL at MW14 for the first time during the Semi-annual Monitoring event completed September 2013 at a concentration of 270 µg/L. Data trends will continue to be evaluated during upcoming sampling events and increasing trends will be closely monitored as part of the Stastical analysis completed on each groundwater data set.
- Lead exceeded its MCL of 15 µg/L in the sample from MW14 (16 µg/L).
- Nitrate exceeded its MCL of 10 µg/L in the sample from MW13S (30 J µg/L).

Eight analytes exceeded their SMCLs:

- Aluminum exceeded its SMCL of 50 µg/L at 14 locations, with concentrations ranging from 55 µg/L (MW07S) to 2,600 µg/L (MW14).

- Chloride exceeded its SMCL of 250 milligrams per liter (mg/L) in the sample from MW19 (310 µg/L).
- Color exceeded its SMCL of 15 Color Units at three locations, with concentrations ranging from 20 Color Units (MW10S) to 600 Color Units (MW12S).
- Iron exceeded its SMCL of 300 µg/L at 13 locations, with concentrations ranging from 350 µg/L (MW105) to 150,000 µg/L (MW12S).
- Manganese exceeded its SMCL of 50 µg/L at 13 locations, with concentrations ranging from 60 µg/L (MW105) to 2,000 µg/L (MW12S).
- Sulfate exceeded its SMCL of 250 mg/l in the sample from MW12S (270 mg/L).
- Odor exceeded its SMCL of 3 threshold odor number (t.o.n.) at five locations, with concentrations ranging from 3.64 t.o.n. (MW07S) to 8.75 t.o.n. (MW19).
- Total Dissolved Solids exceeded its SMCL of 500 mg/L in the sample from MW19 (1,200 mg/L).

4.2 Lower Patapsco Aquifer

4.2.1 Summary of Detections

Positive detections in samples from the LPA include metals, pesticides, VOCs and miscellaneous parameters.

Eleven pesticides, 4,4- dichlorodiphenyldichloroethylene, 4,4-dichlorodiphenyldichloroethane, 4,4- dichlorodiphenyltrichloroethane, alpha-chlordane, beta-bhc, delta-bhc, endosulfan I, endosulfan II, endosulfan sulfate, endrin, and gamma-chlorodane, were detected in the sample from MW13D. No pesticides or herbicides were detected above their respective MCLs.

Twenty-three metals were detected in the LPA samples. Aluminum, barium, beryllium, calcium, cobalt, copper, manganese, nickel, potassium, sodium, and zinc were widespread in the LPA including the upgradient wells MW4DR and MW7D, suggesting these metals are naturally occurring in the aquifer.

Seven VOCs were detected in four samples from LPA wells. PCE and carbon tetrachloride were the only VOC constituents detected above their respective MCL (see section 4.2.2). All other detected VOCs were at concentrations below their respective MCLs.

4.2.2 Summary of Exceedances above Maximum Contaminant Levels and Secondary Maximum Contaminant Levels

The LPA groundwater results were screened against MCLs and SMCLs as shown on **Tables 9 and 10**, respectively. Four analytes detected in samples from LPA wells exceeded their MCLs:

- Two samples (MW7D and MW109D) had metals that exceeded their respective MCLs. Beryllium exceeded its MCL of 4 µg/L in the sample from MW7D at a concentration of 5.2 µg/L. Lead exceeded its MCL of 15 µg/L in the sample from MW109D at a concentration of 44 µg/L.

- Carbon Tetrachloride exceeded its MCL of 5 µg/L in the sample from MW4DR detected at a concentration of 8.6 µg/L.

- PCE exceeded its MCL of 5 µg/L in the sample from MW101D detected at a concentration of 29 µg/L.

Eight analytes detected in samples from the LPA exceeded their SMCLs:

- Aluminum exceeded its SMCL of 50 µg/L in nine wells with concentrations ranging from 78 µg/L (MW12D) to 5,900 µg/L (MW109D).

- Chloride exceeded its SMCL of 250 mg/L in the sample from MW109D detected at a concentration of 470 mg/L.

- Color exceeded its SMCL of 15 color units in the sample from MW109D detected at a concentration of 60 color units.

- Iron exceeded its SMCL of 300 µg/L in six wells, with concentrations ranging from 810 µg/L (MW12D) to 8,500 µg/L (MW10D).

- Manganese exceeded its SMCL of 50 µg/L from seven wells, with concentrations ranging from 71 µg/L (MW13D) to 470 µg/L (MW10D).

- Odor exceeded its SMCL of 3 t.o.n. in the sample from MW10D detected at a concentration of 5.25 t.o.n.

- Total Dissolved Solids exceeded its SMCL of 500 mg/L in the sample from MW109D detected at a concentration of 800 mg/L.

5. Chemical Results – Surface Water

Three surface water samples were collected from the unnamed stream. **Table 11** presents positive surface water detections from samples collected during the March 2014 sampling event. Surface water analytical tables are included in **Appendix E**. Surface water analytical results were screened against State of Maryland Chronic Ambient Water Quality Criteria for Fresh Water and State of Maryland Water Quality Criteria for Human Health for Consumption of Drinking Water.

Three anions (chloride, nitrogen [nitrate], and sulfate) were detected in the surface water. Nineteen metals (aluminum, antimony, arsenic, barium, beryllium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, nickel, potassium, selenium, sodium, vanadium, and zinc) were detected in the surface water samples. No metals were detected above the Maryland Water Quality Criteria.

One VOC, acetone, was detected in the sample collected at SW02 at a concentration of 4.7 µg/L.

6. Statistical Analysis

The analytical data were analyzed statistically with a focus as to how the groundwater quality was changing over time. The historic database included data for 247 analytes in 26 monitoring wells in semi-annual monitoring events dated back to 1994. Previous statistical analyses have divided the data into four groups, three of which were in the Upper Patapsco and one group for all Lower Patapsco data. Interwell comparisons were made between data in a single well designated as background and a group of downgradient wells. In 2009, the USEPA released a Unified Guidance document for the statistical evaluation of groundwater (USEPA, 2009). Following the concepts in that document, the statistical approach presented herein was modified beginning with the first semi-annual monitoring report for 2010. Another modification in the procedure is that the Lower Patapsco is only monitored annually, in the spring. In this section, the following topics are discussed: the present approach, the data preparation, and the results for both groundwater-bearing units.

6.1 Statistical Procedure

The lack of uncontaminated background wells indicated that a proper statistical analysis program would have to be based on intrawell testing. Typical intrawell tests, such as comparison to intrawell upper prediction limits or Shewhart-CUSUM control charts are typically used to compare new data to previous data that represent unimpacted groundwater conditions. This is not possible at this Site because all twenty-six of the wells have some history of detection of manmade chemicals. For these reasons, the best approach is an intrawell test that could measure trends. Mann-Kendall testing was selected as the test for these data. This nonparametric test can evaluate a set of data points in chronological order and determine if an increasing or decreasing slope is a statistically significant trend.

One important parameter in tests for trends is the number of data points selected from the data set. There have been 40 sampling events, two per year since 1994, for many of the constituent-well pairs. With a data set of this size, it is possible to miss a recent trend due to the legacy of twenty years of data. For this reason, a “sliding window” approach with 12 data points was selected as the most appropriate diagnostic approach. Data points representing the 12 most recent sampling events were selected. For the Upper Patapsco, these data points cover the time from the autumn of 2008 to the spring of 2014. For the Lower Patapsco, these data points cover the time from the autumn of 2007 to the spring of 2014. These 12 points were evaluated for each constituent of concern for each well. In each set of semiannual or annual statistical tests, the oldest point is dropped from the test data sets, and the most recent point is added. The statistical tests are conducted on 12 data points, with new points added each sampling event and old ones being removed.

The data were loaded into a groundwater statistical program, Sanitas ™ prepared by Sanitas Technologies in Shawnee, Kansas. Version 9.2.35 (released in 2014) was used. The program was designed to automate the statistical analysis of Resource Conservation and Recovery Act (RCRA) hazardous waste (Subtitle C) and municipal (Subtitle D) landfill groundwater quality data. The program's decision logic guides the user through procedures that ensure that the analysis will meet the requirements of the USEPA, American Society for Testing and Materials, and state regulations. In intrawell testing, there are separate data sets for each combination of monitoring wells and constituents.

As specified above, most of the data sets had 12 members. A small number of analytes, such as1,4-dichlorobenzene, and 1,3,5-trimethylbenzene were not always in the monitoring program and have fewer members. For each data set, three tests were run using Sanitas: an outlier test, a distribution test, and a trend test. In these tests, non-detections were replaced with values equal to half of the detection limit.

Sanitas contains three outlier tests: USEPA Outlier Screening (USEPA, 1989), Dixon's Test, and Rosner's Test. The USEPA Outlier Screening test was used to specify suspect outliers and Dixon's Test was used to determine if the suspect data point was a statistically significant outlier. Dixon's Test is valid for data sets with up to 25 members. Rosner's Test is recommended for larger data sets. Because the data sets in this analysis always had 12 or less data points, Rosner's Test was not used. Both the tests were conducted at a 5% level of significance ($\alpha = 0.05$). All outliers indentified in a data set were listed in the appropriate table. In some cases, a data set had more than one statistically significant outlier. The detection frequency was tabulated. In the event that there were fewer than four detections in a data set, the outliers were not counted.

The Shapiro-Wilk test for normality is recommended by the USEPA for data sets with 50 or fewer members (USEPA, 2009). This test was used to determine if the test data was normally distributed. If the data passed the Shapiro-Wilk test, "Normal" was recorded on the results table. If the data failed the Shapiro-Wilk test, they were logarithmically transformed and retested. If the data passed this test, "Lognormal" was recorded to indicate a lognormal distribution. If the data failed the second test "Unknown" was recorded to indicate that the distribution of the data set was not known. Whenever there were fewer than four detections, the distribution testing indicated an unknown distribution. On the table "NDs" was recorded to indicate that there were too many non-detects to evaluate the true distribution of the data set.

Sen's Slope Estimator was used for each data set in conjunction with the Mann-Kendall test to determine if the slope in the 12 data points was statistically significant at an $\alpha = 0.02$ level. If the slope was significant, a decreasing or increasing trend was indicated on the summary table. Increasing trends were noted in bold font. Trends were counted even in highly censored data sets (having fewer than four detections), but not in cases in which the data set was wholly composed of non-detections.

Descriptive statistics were tabulated for each COC in each monitoring well. These statistics included the number of detections, the number of samples (usually 12), the sample mean, the standard deviation, the variance, the maximum detected value, and the minimum detected value. In computing the mean, the standard deviation and the variance, non-detects were included at half the detection limit.

6.2 Data Preparation

Several steps were taken in order for the data to be input into the Sanitas program. First, qualified data, such as J-flagged values, were accepted as quantitative. Flags were removed and the data were converted to numerical values. No duplicate data points were included in the statistical analysis in order to satisfy the requirement of independence.

As stated above, detection limits were handled in some tests in Sanitas by inserting one half of the detection limit. This presented a practical challenge, because detection limits for non-detections that occurred prior to September 2009 were not available. One option, using "< 0" as an input, will generate a warning flag in Sanitas because such values can create instability in some tests. It was therefore necessary to determine a surrogate detection limit. For all of these data points, the MDLs that were available in the laboratory reports for spring 2010 were used. It was assumed that the MDLs had the same values in previous sampling events. This compromise seemed to work well, except for thallium. For some data sets, a detection limit of 1.0 µg/L from the autumn 2009 data was used as the detection limit instead.

As stated previously, analytes that were never detected or very rarely detected, as well as analytes that appeared to be laboratory contaminants were removed from the statistical analysis. This was necessary in order to minimize the number of tests on data sets composed of detection limits and make the statistical analysis more diagnostic. The decision to remove or keep an analyte was based upon detection frequency in the data base for all sampling events and not just the most recent 12 events.

In preparing the data tables, naphthalene was included with the SVOCs. Four metals (calcium, magnesium, potassium, and sodium) were tabulated with the inorganic parameters rather than the metals. Total 1,2-dichloroethene was excluded in favor of the individual isomers, cis-1,2-dichloroethene and trans-1,2-dichloroethene. The data for the two nitrate entries “nitrate” (measured prior to September 2009) and “nitrate-N” (measured since September 2009) were merged into a single entry designated “nitrate-N”.

6.3 Statistical Results for the Upper Patapsco

The input data sets used in the Sanitas program are included in **Appendix F**. These attachments show the chosen surrogate detection limits and the data points used in computing the statistical results. The metals input data are included in Attachment F-1 in **Appendix F**. Eighteen metals were statistically analyzed including aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, thallium, vanadium, and zinc. Eight inorganic groundwater parameters were analyzed: chloride, nitrate-N, nitrogen, sulfate, calcium, magnesium, potassium, and sodium. These can be found in Attachment F-2. The 17 VOCs included in the statistical analysis were 1,1-dichloroethane, 1,2-dichlorobenzene, 1,2-dichloropropane, 1,3,5-trimethylbenzene, 1,4-dichlorobenzene, benzene, CFC-12, chlorobenzene, chloroethane, cis-1,2-dichloroethene, ethylbenzene, PCE, toluene, total xylenes, trans-1,2-dichloroethene, trichloroethene, and vinyl chloride (Attachment F-3). The two SVOCs can be found in Attachment F-4: 1,4-dichlorobenzene and naphthalene.

The Sanitas output data can also be found in **Appendix F**. The outlier analysis and the normality testing for the Upper Patapsco COCs are included in Attachment F-5. The Sen’s Slope Estimator and Mann-Kendall test results are in Attachment F-6.

Descriptive statistics for the analytes in the Upper Patapsco can be found in **Appendix G**. These statistics are tabulated in Attachments G-1 to G-4 for each of the metals, inorganic analytes, VOCs, and SVOCs, respectively. Only analytes for which statistical analysis was conducted were included in **Appendix G**. Analytes deleted due to low detection frequency were not included.

The statistical results for the metals are summarized in **Table 12**. No statistically significant increasing trends were identified. Thirteen decreasing trends were identified. The concentrations of metals are declining in the Upper Patapsco.

The statistical results for the inorganic constituents are summarized in **Table 13**. Five statistically significant increasing trends were identified: calcium and magnesium in

MW-7S; sulfate and magnesium in MW12S; and sodium in MW107. There were seven statistically significant decreasing trends identified.

The statistical results for VOCs in the Upper Patapsco are summarized in **Table 14**. One statistically significant increasing trend was identified, chlorobenzene in MW-7S. There were eight statistically significant decreasing trends. Thus, the overall concentrations of VOCs are declining in the Upper Patapsco.

The statistical results for SVOCs in the Upper Patapsco are summarized in **Table 15**. No statistically significant increasing or decreasing trends were discernable.

6.4 Statistical Results for the Lower Patapsco

The input data sets used in the Sanitas program for the Lower Patapsco were also included in **Appendix F**. The metals input data are included in Attachment F-7 in **Appendix F**. Eighteen metals were statistically analyzed including aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, nickel, selenium, thallium, vanadium, and zinc. Eight inorganic groundwater parameters were analyzed: chloride, nitrate-N, nitrogen, sulfate, calcium, magnesium, potassium, and sodium. These can be found in Attachment F-8. The seven VOCs included in the statistical analysis were 1,4-dichlorobenzene, benzene, chloroform, cis-1,2-dichloroethene, PCE, toluene, and trichloroethene (Attachment F-9). No SVOCs were statistically analyzed due to low detection frequencies.

The Sanitas output can be found in **Appendix F**. The outlier analysis and the normality testing for the Lower Patapsco COCs are included in Attachment F-10. The Sen's Slope Estimator and Mend-Kendall test results are in Attachment F-11.

Descriptive statistics for the analytes in the Lower Patapsco can be found in **Appendix G**. These statistics are tabulated in Attachments G-5 to G-7 for each of the metals, inorganic analytes, and VOCs, respectively. Only analytes for which statistical analysis was conducted were included in **Appendix G**. Analytes deleted due to low detection frequency were not included.

The statistical results for the metals are summarized in **Table 16**. Twenty-six statistically significant increasing trends were identified out of 180 data sets. Six of the increasing trends are in MW109D. MW7D and MW108D had the next highest number of increasing trends at four each. Barium exhibited a statistically significant increasing trend in five wells.

The statistical results for the inorganic constituents are summarized in **Table 17**. Seventeen statistically increasing trends were identified out of 80 data sets. Two inorganic constituents were increasing in the background well, MW7D. MW4DR had five statistically significant increasing trends (out of eight parameters). MW13D had four increasing trends. There was only one decreasing trend.

The statistical results for VOCs in the Lower Patapsco are summarized in **Table 18**. Two statistically significant increasing trends were identified; both were in MW101D. These two trends, for cis-1,2-dichloroethene and PCE, were also exhibited in the previous statistical analysis. The increasing analytes are members of the PCE biodegradation chain, and their concentrations continue to be somewhat proportional. Four statistically significant decreasing trends were identified, three of which were in MW4DR.

The large number of increasing trends for conservative substances, such as the metals and ions, and the relatively small number of increasing trends in the VOCs supports the conclusion that the LPA is not connected hydraulically to the UPA as described in the CSL Remedial Investigation Report (EM, 2007).

6.5 Observations and Interpretation

This section presents an interpretation of the statistical analysis completed at the CSL. The notable observations include:

- The UPA samples had five statistically significant increasing inorganic constituent trends and one increasing VOC trend.

- One increasing trend (chlorobenzene) was observed in VOC and SVOCs concentrations in the UPA but there were eight decreasing trends for VOCs. The larger number of decreasing trends and the lower number of detections compared to the previous sampling event indicate that groundwater VOC impacts in the UPA are declining.

- The low detection frequencies of the constituents from the UPA provide additional evidence that the LPA is not connected hydraulically to the UPA.

- Detection monitoring parameters were detected above MCLs in the UPA samples listed below. No increasing or decreasing trends were observed at any of those locations.

  - Nitrate in MW-13S
  - Arsenic in MW-07S,MW-12S, MW-14, MW-18, and MW-19
  - Cadmium in MW-14
  - Chromium in MW-14
  - Lead in MW-14
  - Benzene in MW-19

- Results from the LPA indicate 26 increasing metal trends and 17 increasing inorganic constituent trends.

- Two statistically significant VOC increasing trends were identified in LPA; both were in MW101D.

- Detection monitoring parameters were above the MCL in four LPA samples, beryllium in MW7D, carbon tetrachloride in MW4DR, lead in MW-109D, and PCE in MW-101D. An increasing trend was also observed at two locations, lead in MW-109D and PCE in MW-101D.

- Aluminum, iron, and manganese were often detected above their respective secondary drinking water standards.

The absence of patterns and correlation in the UPA and LPA sample analytical results supports the Remedial Investigation conclusion that the units are separated by the Middle Patapsco clay, which is a thick and effective confining unit (EM, 2007). That most trends are increasing in the LPA and decreasing in the UPA also supports this conclusion; the concentrations of monitored groundwater constituents in the two water bearing units are progressing in opposite directions.

7. Conclusion and Recommendations

7.1 Summary of March 2014 Monitoring Results

The results of the March 2014 groundwater and surface water monitoring are consistent with the results of prior sampling events. MCL exceedances were sporadic and isolated and include benzene and arsenic, concentrations of which exceeded their respective MCLs in samples from the UPA mainly at the southeast corner of Cell 1. At MW14, cadmium, chromium, and lead MCL exceedances were also observed and nitrate exceeded its MCL at MW13. In the LPA, beryllium and lead exceeded their respective MCLs at MW7D and MW109D, respectively. PCE and carbon tetrachloride concentrations exceeded their MCLs in the samples from MW101D and MW4DR, respectively. Historical data for all sampling rounds completed to date are provided in **Appendix H**.

7.1.1 Monitoring in the Upper Patapsco Aquifer

Groundwater sampling activities have been completed under the monitoring requirements for the UPA. Arsenic, benzene, and nitrate are constituents detected in samples from the UPA that have concentrations exceeding MCLs during the March 2014 event and have exceeded MCLs previously; data trend plots for arsenic and benzene concentrations in selected UPA wells are provided as **Figures 7 and 8**, respectively. The trend plots visually display constituent concentrations at selected sampling locations since sampling activities commenced. Neither constituent shows an increasing trend. Statistical analysis shows increasing trends in other constituents detected in samples from the UPA; however, none of these constituents exceeded their MCLs.

A general assessment of the UPA indicates that samples with constituents exceeding their MCLs are generally collected from wells south of landfill Cell 1 and wells located between the cells and the railroad right of way. The occasional historical detections of other compounds are in samples from wells from the same part of the Site.

7.1.2 Monitoring in the Lower Patapsco Aquifer

Groundwater sampling activities have been completed under the monitoring requirements for the LPA. PCE in the sample from MW101D, carbon tetrachloride in the sample from MW04DR, beryllium in the sample from MW07D, and lead in the sample from MW109D exceeded their respective MCLs. A data trend plot for PCE is provided as **Figure 9**.

7.1.3 Monitoring in Surface Water

Three surface water samples were collected during the March 2014 monitoring event. Constituent detections in these samples are summarized in Section 5. No metals were detected at concentrations exceeding State of Maryland Water Quality Criteria. One VOC, acetone, was detected in the sample from SW02 at a concentration below the State of Maryland Water Quality Criteria.

7.1.4 Comparison of Monitoring Results in the Upper and Lower Patapsco Aquifers

PCE, with historical MCL exceedances in the LPA, have been detected generally in only trace concentrations in the UPA. Carbon tetrachloride, consistently detected in MW4DR in the LPA, has never been detected in samples collected from the UPA. Fuel constituents including benzene and ethylbenzene that have been detected in several UPA wells along the east side of the landfill are infrequent trace detections in the LPA. Certain inorganic analytes, most notably arsenic, are persistent in the UPA, but are detected infrequently and at trace concentrations in samples from the LPA.

7.2 Evaluation of the Adequacy of the Monitoring Well Network

7.2.1 Upper Patapsco Aquifer Monitoring Wells

The groundwater monitoring well network for the UPA consists of 16 shallow monitoring wells. These wells are located along the periphery of the waste cells and around the CSL property boundary. Three of the shallow monitoring wells are located southeast of the landfill and off FGGM property. Sampling of these three shallow wells has indicated that constituents detected in the shallow groundwater at the landfill have not migrated an appreciable distance southeast of the installation boundary within the UPA. In order to further characterize shallow UPA groundwater off-post, groundwater samples were collected from a series of soil borings installed in Anne Arundel County Right-of-Way southeast of the Amtrak property. Sampling methodology and analytical results are presented in the June 2014 Draft *Focused Feasibility Study/Assessment of Corrective Measures*.

7.2.2 Lower Patapsco Aquifer Monitoring Wells

The groundwater monitoring network for the LPA consists of ten wells. These wells are located northwest and southeast of the waste cells and landfill property boundary. Groundwater flow in the LPA in this area is from the northwest to the southeast. Based on the existing monitoring well network, three of the deep monitoring wells are located hydraulically upgradient of the landfill. Two of the deep monitoring wells are located crossgradient and five are located downgradient. Three of the deep monitoring wells are located southeast of the landfill and off FGGM property.

Sampling of the deep wells has indicated the presence of constituents. However, these constituents are not related to those detected in samples from the UPA as described in the statistical analysis section (Section 6). Additionally, the Remedial Investigation Report (EM, 2007) documented the presence and effectiveness of the Middle Patapsco Clay as a hydraulic barrier between the Upper and Lower Patapsco aquifers. Although the locations of the LPA wells surround the CSL in areal extent, they do not serve to monitor potential releases to groundwater from the CSL.

It is noted that the LPA is now being handled under a separate Comprehensive Environmental Response, Compensation, and Liability Act Operable Unit (Operable Unit 4 / LPA) and will have its own detailed Remedial Investigation, Feasibility Study, Proposed Plan, and Record of Decision.

An Addendum to the CSL Monitoring Plan dated 20 June 2012 was prepared in response to comments dated 6 April 2012 from the Maryland Department of the Environment (MDE) that agreed to the reduction of monitoring frequency of the ten deep LPA wells from semi-annual to annual. Deep LPA groundwater monitoring wells will continue to be monitored on an annual basis moving forward. The correspondence from MDE dated 6 April 2012 also noted that once a corrective action has been approved for Operable Unit 4 / LPA, a request to discontinue monitoring of the deep LPA wells under the CSL Monitoring Program will be re-evaluated. The revised CSL Monitoring Plan reflecting these changes was submitted on 25 February 2013.

Pesticides	8081B	1,000mL Glass	Cool to 4º C
Mercury	7470A	500 mL Plastic	pH <2 HNO3
SVOCs	8270D	1,000mL Glass	Cool to 4º C
TAL Metals	6010C	500 mL Plastic	pH <2 HNO3
VOCs	8260	40 mL Glass	pH <2 HCL

Wet Chemistry			
Analyte	**EPA Analytical Method**	**Sample Container**	**Preservative**
Alkalinity	SM2320B	250 mL Plastic	Cool to 4º C
Ammonia - N	350.1	250mL Plastic	pH <2 H2SO4
Chemical Oxygen Demand	SM5220D	250mL Plastic	pH <2 H2SO4
Chloride	300.1	250mL Plastic	Cool to 4º C
Color	SM2120B	500mL Plastic	Cool to 4º C
Cyanide	9012B	250mL Plastic	pH >12 NaOH
Hardness	SM2320C	250mL Plastic	pH <2 HNO3
Odor	2150	500mL plastic	Cool to 4º C
pH	SM2400-HB	100mL Plastic	Cool to 4º C
Specific Conductance	120.1	250mL Plastic	Cool to 4º C
Sulfate	300.1	250mL Plastic	Cool to 4º C
Sulfide	SM4500-S2F	500mL Plastic	Zinc Acetate, pH>9 NAOH
Total Dissolved Solids	SM2540C	250mL Plastic	Cool to 4º C
Turbidity	180.1	250mL Plastic	Cool to 4º C

Notes:
EPA - United Stated Environmental Protection Agency
mL - milliliter
º C - degrees Celsius
PCB - polychlorinated biphenyl
SVOC - semi-volatile organic compound
TAL metals - Target Analyte List Metals
VOC - volatile organic compound
HNO3 - Nitric Acid
H2SO4 - Sufluric Acid
HCL - Hydrochloric Acid
NaOH - Sodium Hydroxide

Trend	No	No	No	No	No	No	No	No	No	No	No	No	No	No	No	No	No	No

Footnotes:

Detection Freq. is the detection frequency.

If more than one outlier is found, the number is indicated in parentheses after "Yes."

NDs indicates that there was an insufficient number of detections to determine the distribution.
If the number of detections was 3 or fewer, any "outlier" reported by SANITAS was ignored, and the distribution was reported as ND, regardless of the findings of SANITAS.

If the Mann-Kendall test did not indicate a statistically significant trend, "No" was recorded for trend.
If the trend was statstically significant but decreasing, then "Decreasing" was indicated.
If the trend was statstically significant and increasing, then "**Increasing**" was indicated in **bold font**.

Detection Freq.	12	12	0	10	12	8	10	12
Trend	**Increasing**	No	No	No	No	No	No	**Increasing**

Footnotes:

Detection Freq. is the detection frequency.

If more than one outlier is found, the number is indicated in parentheses after "Yes."

NDs indicates that there was an insufficient number of detections to determine the distribution.

If the number of detections was 3 or fewer, any "outlier" reported by SANITAS was ignored, and the distribution was reported as ND, regardless of the findings of SANITAS.

If the Mann-Kendall test did not indicate a statistically significant trend, "No" was recorded for trend.

If the trend was statstically significant but decreasing, then "Decreasing" was indicated.

If the trend was statstically significant and increasing, then "**Increasing**" was indicated in **bold font**.
